1 Ring

Recall that a group is a set equipped with a binary operation. However, often times, a lot of sets are naturally endowed with *two* binary operations: addition *and* multiplication. In this case, we want to account for *both* of them at the same time instead of having two groups with the same sets but different operations. To that, we introduce the *ring*.

1.1 The Ring: Definition

Definition 1.1: Ring

A ring R is a set with two binary operations, addition (denoted by $a+b$) and multiplication (denoted by ab), such that for all $a, b, c \in R$:

1. $a + b = b + a$
2. $(a + b) + c = a + (b + c)$
3. There is an additive identity $0 \in R$ such that $a + 0 = 0 + a = a$ for all $a \in R$.
4. There is an element $-a \in R$ such that $a + (-a) = 0$.
5. $a(bc) = (ab)c$.
6. $a(b + c) = ab + ac$ and $(b + c)a = ba + ca$.

Remarks:

- A ring is an abelian group under addition, but also has an associative multiplication that is *left and right distributive* over addition.
- Multiplication does **not** have to be commutative. If it is commutative, we say that the ring is commutative.
- A ring does not have an identity under multiplication. A *unity* (or identity) in a ring is a *nonzero element* that is an identity under multiplication.
- A nonzero element of a commutative ring with unity need not have a multiplicative inverse. When it does, we say that it is a *unit* of the ring. In other words, a is a unit if a^{-1} exists.
- If a and b belong to a commutative ring R and a is nonzero, then we say that a *divides* b (or that a is a factor of b) and write $a|b$ if there exists $c \in R$ such that $b = ac$. If a does not divide b, we write $a \nmid b$.
- If we need to deal with something like:
$$\underbrace{a + a + \cdots + a}_{n \text{ times}}$$
Then, we will use $n \cdot a$ to mean this.

1.2 Basic Applications of the Ring

Here, we introduce several examples of rings.

1.2.1 Example 1: Integers

$$\mathbb{Z} = \{\ldots, -2, -1, 0, 1, 2, \ldots\}$$

The set of integers under ordinary addition and multiplication is a commutative ring with unity 1. The *units* of $\mathbb{Z}$ are 1 and -1.

1.2.2 Example 2: Integers Mod N

$$\mathbb{Z}_n = \{0, 1, \dots, n-1\}$$

The set of integers modulo n under addition and multiplication is also a commutative ring with unity 1. The set of *units* is $U(n)$. Here, we define $U(n)$ to be the set of integers less than n and relatively prime to n under multiplication modulo n.

1.2.3 Example 3: Polynomials

The set $\mathbb{Z}[x]$ of all polynomials in the variable x with integer coefficients under ordinary addition and multiplication is a commutative ring with unity $f(x) = 1$.

1.2.4 Example 4: Matrices

The set $M_2(\mathbb{Z})$ of 2×2 matrices with integer entries is a *noncommutative ring* with unity $\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$.

1.2.5 Example 5: Even Integers

The set $2\mathbb{Z}$ of even integers under ordinary addition and multiplication is a commutative ring <u>without</u> unity.

1.2.6 Example 6: Direct Sum

If $R_1, R_2, \dots, R_n$ are rings, then we can create a new ring like so:

$$R_1 \oplus R_2 \oplus \cdots \oplus R_3 = \{(a_1, a_2, \dots, a_n) \mid a_i \in R_i\}$$

From this, we can perform componentwise addition and multiplication; that is:

$$(a_1, a_2, \dots, a_n) + (b_1, b_2, \dots, b_n) = (a_1 + b_1, a_2 + b_2, \dots, a_n + b_n)$$

$$(a_1, a_2, \dots, a_n)(b_1, b_2, \dots, b_n) = (a_1 b_1, a_2 b_2, \dots, a_n b_n)$$
